

FILE INDEX

Casey Burklow, Isaac Dudney, KC Guzman, Matthew Hinze

FORMAT:

`/location/ Filetype`

`file.extension` - description

`/ PHP files`

`additem.php` - The PHP function to add a new product listing (item) to the database. Uses a form to accept the needed data.

`admin.php` - Admin management page. Written in PHP, sending SQL commands with escalated privilege.

`bid.php` - Server-side logic for updating bid information on an item. No userfacing code is in this script.

`dash-2.php` - Profile page. Doubles as user preferences page if logged in. Has a list of items that user has created, and preferences if the user is logged in.

`dash.php` - Fallback for the previous; less featured but known-stable so we keep it just in case. UNUSED.

`deleteitem.php` - Serverside script for deleting an item, requires the user to be the original poster or an admin to be deleted.

`deleteuser.php` - Serverside script for deleting a user, requires the user to be an admin to be deleted.

`edititem.php` - Item edit page for the user that submitted it, in case they

want to change the tags/description/title of the work. This is purely the user-facing side of the function, no backend stuff happens here.

`index.php` - Main page. Includes the slideshow for the featured items.

`logout.php` - Literally just a link to log the user out.

`moditem.php` - Serverside script for editing item, `edititem.php` calls this function to execute the actual edit (no logic stored in `edititem.php`, it's just userfacing code).

`newitem.php` - Form to add a new item to the database.

`product.php` - Main page for an item, this is what happens if you click on a title in a search.

`search.php` - Logic for search form in the header. Searches through database for text entered into form.

`updateuser.php` - Logic for updating user information, includes server-side logic and submits to itself.

/ CSS files

`index.css` - primary CSS for the main body of every page; most of the pages share CSS elements, so it's more efficient to reference just one for the body. There is a separate one for the header.

/classes/ PHP files

`password.php` - Hashes the password for storage on the server; since it's a big security risk to store plaintext passwords, we hash the passwords and store the hashes in the server's database.

`user.php` - enters user data into server's database, including password hash.

/includes/ PHP files

`config.php` - Configuration for the server. Includes PDO connection, time-zone, email address, database IP address, and more.

/layout/ PHP files

`footer.php` - Global footer file. Inserted at the end of the index page, unneeded on other webpages.

`header.php` - Global header file. Includes login form, search form, hero banner, logo, categories drop down.

/layout/ CSS files

`index.css` - Header/footer CSS file. Includes media queries to ensure RWD for the entire header down to original iPhone width screens.
